- From the given resource we need to develop tomato leaf disease detection
- So you can refer the given dataset and github code which already contains the model schema
- No need to make mobile app
- So, instead of using CNN model use MobileNetV3-Small 0r Large
- Instead of webpage saying late blight make it display disease, confidence, severity, and affected area
- Add explainable Ai such as Grad-CAM so that it gives the explaination about the disease also
- The given github contains a public village dataset and we have a kaggle data set i,e tomato leaf disease dataset . Now, I want you to create a model which compares both the dataset
